

Unison UK-Silica

Aqueous to Non-aqueous, Normal Phase

Normal Phase for Retention of Polar Compounds

Unison UK-Silica, 250 x 2 mm
acetonitrile / 20mM ammonium acetate = 90 / 10
0.2 mL/min, 37 °C 260 nm

Unison has numerous stationary phases including C18, C8, phenyl, silica and aminopropyl.

For normal phase separation, Unison offers silica and aminopropyl columns.

Offering dramatically higher resolution than conventional 5µm columns, the Unison UK series provides authoritative normal phase separation with a silica stationary phase.

In addition to normal phase mode, Unison UK-Silica is optimal for the separation of high-polarity compounds under aqueous normal phase conditions.

The nucleotide separation example above provides a demonstration of Unison UK Silica's power. It shows the separation of an eluent containing a high concentration of acetonitrile with an aqueous solution of ammonium acetate added. In this manner, UK-Silica is excellent for LC-MS and the separation of highly polar compounds when retention on a traditional ODS phase is poor.
